The reaction of a compound of formula II with an acid of formula III in accordance with embodiment (a) of the process can be carried out in accordance with methods known per se in peptide chemistry. Thus, when an acid of formula III is used, the reaction is preferably carried out in the presence of a condensation agent such as hydroxybenzotriazole and dicyclohexylcarbodiimide. This reaction is conveniently carried out in an inert organic solvent such as an ether (e.g. diethyl ether, tetrahydrofuran etc) or dimethylformamide at a low temperature, suitably at about -10°C to +5°C and especially at about 0°C. Suitable reactive derivatives of acids of formula III which can be used are, for example, the corresponding acid halides (e.g. acid chlorides), acid anhydrides, mixed anhydrides, activated esters etc. When a reactive derivative is used, the reaction is conveniently carried out in an inert organic solvent such as a halogenated aliphatic hydrocarbon (e.g. dichloromethane etc) or an ether (e.g. diethyl ether, tetrahydrofuran etc) and, where appropriate, in the presence of an organic base (e.g. N-ethylmorpholine, diisopropylethylamine etc) at a low temperature, suitably at about -10°C to +5°C and especially at about 0°C.

The reduction of a compound of formula I in which R⁵ and R⁶ together represent oxo in accordance with embodiment (b) of the process can be carried out according to methods known per se for the reduction of a carbonyl group to a hydroxy group. Thus, for example, the reduction can be carried out using a complex metal hydride such as an alkali metal borohydride, especially sodium borohydride, in an appropriate organic solvent such as an alkanol (e.g. methanol, ethanol, propanol, isopropanol etc). Conveniently, the reduction is carried out at about room temperature.

In accordance with embodiment (c) of the process, suitable agents which yield an alkanoyl, cycloalkyl-carbonyl, aralkanyl, aroyl, heterocyclylcarbonyl, alkylsulphonyl, cinnamoyl or α-aralkoxycarbonylaminoal-kanoyl group are the corresponding acids or reactive derivatives thereof such as the corresponding acid halides (e.g. acid chlorides), acid anhydrides, mixed anhydrides, activated esters etc and suitable agents which form a cyclic imide group of formula (a) hereinbefore are compounds of the formula HOOC-P-Q-COOAralkyl in which P and Q have the significance given earlier. The reaction of a compound of formula IV with the aforementioned agents is carried out in the same manner as that described earlier in connection with embodiment (a) of the process. In the reaction of a compound of formula IV with a compound of the formula HOOC-P-Q-COOAralkyl, the initially formed reaction product spontaneously loses a molecule of aralkanol (HO-Aralkyl) with the formation of the cyclic imide group.

The reaction of a compound of formula IV with a compound of formula V in accordance with embodiment (d) of the process can be carried out in a manner known per se. Thus, the reaction is conveniently carried out in an inert organic solvent such as a halogenated aliphatic hydrocarbon (e.g. dichloromethane etc) at a temperature between about 0°C and room temperature, preferably at room temperature.

The oxidation in accordance with embodiments (e), (f), (g) and (h) of the process can be carried out according to known procedures. The oxidation is preferably carried out using an organic peracid such as peracetic acid, perbenzoic acid, a haloperbenzoic acid such as m-chloroperbenzoic acid, perphthalic acid or the like, although it can also be carried out using hydrogen peroxide. The oxidation is conveniently carried out in the presence of an organic solvent which is inert under the reaction conditions, for example an alkanol such as methanol, ethanol etc, a halogenated hydrocarbon such as methylene chloride etc, and the

like. The oxidation can be carried out within a wide temperature range, for example a range between about -70 °C and about room temperature.

The catalytic hydrogenation in accordance with embodiment (i) of the process can be carried out in a known manner. Conveniently, the catalytic hydrogenation is carried out in the presence of a noble metal catalyst, preferably a palladium catalyst such as palladium-on-carbon, and in an inert organic solvent (e.g. an alcohol such as ethanol, isopropanol etc) at about room temperature and under atmospheric pressure. When a compound of formula I in which R¹ represents nitro-substituted cinnamoyl and R² represents hydrogen is catalytically hydrogenated according to this embodiment, then there is obtained a compound of formula I in which R¹ represents amino-substituted hydrocinnamoyl and R² represents hydrogen.

Embodiment (j) of the process can be carried out using a strong inorganic acid, for example a hydrohalic acid such as hydrogen chloride or hydrogen bromide, or a strong organic acid, for example a halogenated alkanecarboxylic acid such as trifluoroacetic acid and the like. This embodiment can be carried out according to known procedures; for example in the presence or absence of an inert organic solvent (e.g. an alkanecarboxylic acid ester such as ethyl acetate etc) and at a temperature between about 0 °C and about room temperature, preferably at about room temperature.

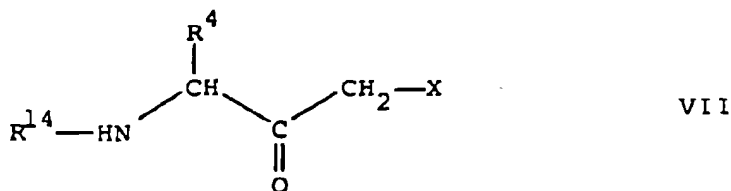

The acylation of a compound of formula VI in accordance with embodiment (k) of the process can be carried out according to methods known per se. Conveniently, the acylation is carried out using an acyl halide such as an acyl chloride or bromide in the presence of an inert organic solvent such as dimethylformamide etc and at a temperature between about 0 °C and room temperature. In place of an acid halide there can, of course, also be used a different reactive acid derivative such as an acid anhydride or the like.

The optional separations in accordance with embodiments (l) and (m) of the process can be effected according to conventional methods; for example, by column chromatography, thin-layer chromatography, high pressure liquid chromatography etc.

The conversion of a compound of formula I into a pharmaceutically acceptable acid addition salt in accordance with embodiment (n) of the process can be carried out by treating such a compound in a conventional manner with an inorganic acid, for example a hydrohalic acid such as hydrochloric acid or hydrobromic acid, sulphuric acid, nitric acid, phosphoric acid etc, or with an organic acid such as acetic acid, citric acid, maleic acid, fumaric acid, tartaric acid, methanesulphonic acid, p-toluenesulphonic acid etc.

The compounds of formula II which are used as starting materials in embodiment (a) of the process are novel and also form an object of the present invention.

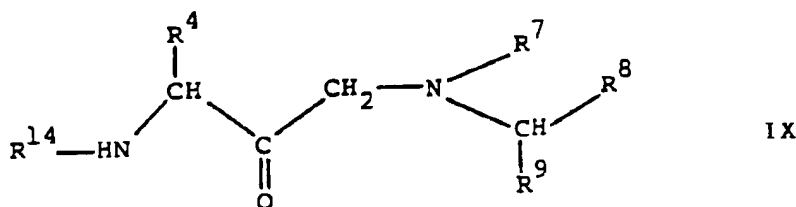

The compounds of formula II can be prepared, for example, by reacting a compound of the general formula

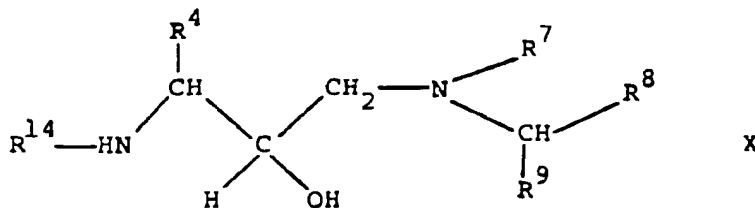

wherein R⁴ has the significance given earlier, R¹⁴ represents an amino-protecting group (e.g. tert.butoxycarbonyl or benzyloxycarbonyl) and X represents a chlorine or bromine atom, with a compound of the general formula

wherein R⁷, R⁸ and R⁹ have the significance given earlier,
and either cleaving off the group R¹⁴ from the resulting compound of the general formula

wherein R⁴, R⁷, R⁸, R⁹ and R¹⁴ have the significance given earlier,
to give a compound of formula II in which R⁵ and R⁶ together represent oxo or reducing the compound of
formula IX and cleaving off the group R¹⁴ from the resulting compound of the general formula

wherein R⁴, R⁷, R⁸, R⁹ and R¹⁴ have the significance given earlier, to give a compound of formula II in which R⁵ represents hydrogen and R⁶ represents hydroxy.

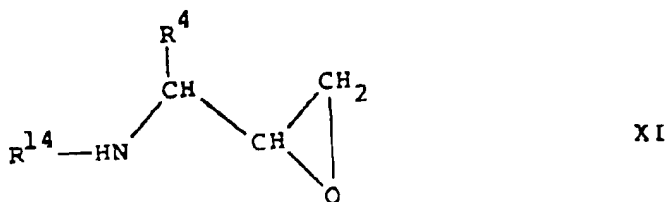

The reaction of a compound of formula VII, preferably one in which R¹⁴ represents benzyloxycarbonyl, with a compound of formula VIII can be carried out in a known manner; for example, in an inert organic solvent such as a halogenated aliphatic hydrocarbon (e.g. dichloromethane etc) and in the presence of a base (e.g. a trialkylamine such as triethylamine etc), conveniently at about room temperature.

The cleavage of the group R¹⁴ from a compound of formula IX can also be carried out in a known manner; for example, using a strong inorganic acid such as a hydrohalic acid or a strong organic acid (e.g. trifluoroacetic acid etc), conveniently at about 0°C to about room temperature. Alternatively, a hydrogenolytically-cleavable amino-protecting group R¹⁴ can be cleaved off using hydrogen in the presence of a noble-metal catalyst (e.g. a palladium catalyst such as palladium-on-carbon) in an organic solvent or solvent mixture which is inert under the reaction conditions (e.g. an alcohol such as ethanol, isopropanol etc, an alkanecarboxylic acid ester such as ethyl acetate, etc) and conveniently at about room temperature.

The reduction of a compound of formula IX to give a compound of formula X can be carried out as described earlier in connection with the reduction of a compound of formula I in which n stands for zero and R⁵ and R⁶ together represent oxo in accordance with embodiment (b) of the process of the invention.

The cleavage of the group R^{14} from a compound of formula X can be carried out in a manner analogous to that described earlier in connection with the cleavage of the group R^{14} from a compound of formula IX.

A further method for the preparation of compounds of formula II in which R⁵ represents hydrogen and R⁶ represents hydroxy comprises firstly reacting a compound of the general formula

wherein R^4 and R^{14} have the significance given earlier, with a compound of formula VIII hereinbefore, conveniently in an inert organic solvent such as an alcohol (e.g. methanol etc), dimethylformamide or the like and at an elevated temperature, conveniently at about 60 °C to about 120 °C, and then cleaving off the group R^{14} in the reaction product (a compound of formula X hereinbefore) as described earlier.

The compounds of formula IV which are used as starting materials in embodiments (c) and (d) of the process are novel and form a further object of the present invention.

The compounds of formula IV can be prepared, for example, by cleaving off the benzyloxycarbonyl or tert.butoxycarbonyl group R^1 from a compound of formula I in which n stands for zero, R^1 represents benzyloxycarbonyl or tert.butoxycarbonyl and R^2 represents hydrogen. This cleavage is carried out in a manner analogous to that described earlier in connection with the cleavage of the group R^{14} from a compound of formula IX.

The compounds of formula VI wherein R^7 and R^8 together represent a trimethylene or tetramethylene group in which one $-CH_2-$ group is replaced by $-NH-$, are used as starting materials in embodiment (k) of the process. The compounds of formula VI wherein R^7 and R^8 together represent a trimethylene or tetramethylene group which is substituted by amino, which are also used as starting materials in embodiment (k) of the process, are novel and also form an object of the present invention. They can be prepared, for example, by cleaving off the alkoxycarbonyl group from a compound of formula I in which R^7 and R^8 together represent a trimethylene or tetramethylene group which is substituted by alkoxycarbonylamino. The cleavage can be carried out according to conventional procedures; for example, by treatment with an acid such as a hydrogen halide (e.g. hydrogen chloride) in an inert organic solvent (e.g. an alkanecarboxylic acid ester such as ethyl acetate etc).

The starting materials of formula III and their reactive derivatives, the starting materials of formula V as well as the compounds of formulae VII, VIII and XI hereinbefore, insofar as they are not known compounds or analogues of known compounds, can be prepared in a similar manner to the known compounds or as described in the Examples hereinafter or in analogy thereto. Moreover, the agents used in embodiment (c) of the process are generally known compounds.

As mentioned earlier, the compounds of formula I and their pharmaceutically acceptable acid addition salts inhibit proteases of viral origin and are useful in the treatment or prophylaxis of viral infections, particularly of infections caused by HIV and other retrovirus.

The in vitro inhibition of HIV protease by the compounds provided by the present invention can be demonstrated by means of the following test:

HIV protease was expressed in *E. coli* and partially purified from soluble extracts of the bacterium by ammonium sulphate fractionation (0-30%). Protease activity was assayed using the protected hexapeptide succinyl-Ser-Leu-Asn-Tyr-Pro-Ile isobutylamide as the substrate. Cleavage of the substrate was quantified by measuring the production of H-Pro-Ile isobutylamide by the spectrophotometric assay of N-terminal proline.

1.25 mM of substrate were dissolved in 125 mM of citrate buffer (pH 5.5) containing 0.125 mg/ml of Tween 20. 10 μ l of a solution of various concentrations of the test compound (dissolved in methanol or dimethyl sulphoxide and diluted with water containing 0.1% Tween 20) and 10 μ l of protease were added to 80 μ l of the above buffered substrate. Digestion was carried out at 37 °C for a fixed period of time and was terminated by the addition of 1 ml of colour reagent [30 μ g/ml of isatin and 1.5 mg/ml of 2-(4-chlorobenzoyl)benzoic acid in 10% acetone in ethanol (vol./vol.)]. The solution was heated in a water bath and then the pigmented residues were re-dissolved in 1 ml of 1% pyrogallol in 33% water in acetone (wt./vol./vol.). The optical density of the solution was measured spectrophotometrically at 599 nm. The formation of H-Pro-Ile isobutylamide in the presence of the test compound was compared with controls and the concentration of test compound required to give 50% inhibition (I_{50}) was determined by means of a graph plotted from the various concentrations of test compound used.

The results obtained in the foregoing test using representative compounds of formula I as the test compound are compiled in the following Table.

The compounds of formula I and their pharmaceutically acceptable acid addition salts can be used as medicaments (e.g. in the form of pharmaceutical preparations). The pharmaceutical preparations can be administered enterally such as orally (e.g. in the form of tablets, coated tablets, dragees, hard and soft
 50 gelatine capsules, solutions, emulsions or suspensions), nasally (e.g. in the form of nasal sprays) or rectally (e.g. in the form of suppositories). However, the administration can also be effected parenterally such as intramuscularly or intravenously (e.g. in the form of injection solutions).

For the manufacture of tablets, coated tablets, dragees and hard gelatine capsules the compounds of formula I and their pharmaceutically acceptable acid addition salts can be processed with pharmaceutically
 55 inert, inorganic or organic excipients. Lactose, maize starch or derivatives thereof, talc, stearic acid or its salts etc can be use, for example, as such excipients for tablets, dragees and hard gelatine capsules.

Suitable excipients for soft gelatine capsules are, for example, vegetable oils, waxes, fats, semi solid and liquid polyols etc.

Suitable excipients for the manufacture of solutions and syrups are, for example, water, polyols, saccharose, invert sugar, glucose etc.

It will, however, be appreciated that the upper limit given above can be exceeded when this is found to be indicated.

Stirring was continued for 2 hours and the mixture was allowed to come to room temperature. The mixture was diluted with water and then extracted with diethyl ether. The aqueous layer was acidified with 4 ml of concentrated hydrochloric acid and extracted with ethyl acetate. The ethyl acetate extracts were back-washed with water. The combined ethyl acetate extracts were dried over sodium sulphate, filtered, evaporated and triturated with petroleum ether (boiling point 40-60 °C) to give 7.5 g of N-(benzyloxycarbonyl)-3-(2-naphthyl)-L-alanine of melting point 109-111 °C.

Then, the solvent was removed by evaporation at room temperature and the resulting white solid was dried and freed from entrained hydrogen chloride in a vacuum over sodium hydroxide for 2 hours. The resulting benzyl [3-chloro-1(S)-[(2-naphthyl)methyl]-2-oxopropyl] carbamate was used immediately in the next step.
- (iv) The foregoing benzyl [3-chloro-1(S)-[(2-naphthyl)methyl]-2-oxopropyl] carbamate was dissolved in 100 ml of 10% aqueous tetrahydrofuran, cooled to 0 °C and treated with 0.456 g of sodium borohydride which was added carefully as the solid.
